

Skimble — How the Architecture Works

A high-level walkthrough of the request & data flow across the AWS deployment

How it works — follow the numbered steps ① → ⑥ in the diagram above

- | | | |
|---|--|--|
| ① Frontend delivery
AWS Amplify builds and serves the React + Vite single-page app over global HTTPS, with CI/CD on every push. | ② Authentication
The user signs in through Amazon Cognito (OAuth2 / OIDC). The app receives a signed JWT access token. | ③ API requests
The SPA calls the AWS Lambda backend (Express) with Axios, attaching the JWT as a Bearer token. |
| ④ Token verification
Lambda validates every JWT against Cognito public keys before authorizing the request. | ⑤ Data persistence
Lambda reads and writes notes and whiteboard sessions in Amazon DynamoDB via the AWS SDK. | ⑥ Realtime sync
Live edits stream over Socket.IO WebSockets through Lambda and broadcast to every session participant. |
